The model of the atom made by Neil Bohr depicts a positively charged nucleus surrounded by a negatively charged ring of electrons that travel in circular orbits. It was a large advancement in the field because Bohr's model described, for the first time, that an electron must absorb or omit energy to move between orbits.

Unfortunately, despite Bohr ' s remarkable achievement in deriving a theoretical expression for the Rydberg constant, he was unable to extend his theory to the next simplest atom, He, which only has two electrons. Bohr ' s model was severely flawed, since it was still based on the classical mechanics notion of precise orbits, a concept that was ...

Bohr uses Ryberg's formula for explaining how the electrons emit light as they move from one orbital to another. The point Bohr was trying to get across is that energy is not continuous in an atom. We can say that an atom that is in the lowest energy level is in the ground state, and when it moves to a higher level it is in an excited state.

The final area of trouble is in creating the Bohr model of the neutral atom. When this is done incorrectly, students can not ascertain the correct changes to become an ion. For next year, I plan on altering this activity. I would provide the Bohr model and particle information for the period 2 neutral atoms.
